

*Application
for
United States Letters Patent*

To all whom it may concern:

Be it known that, we,

Dirk Lichtblau, Nina Berova, John Berger and Koji Nakanishi

have invented certain new and useful improvements in

METHOD FOR ISOLATING TERPENE TRILACTONES (GINKGOLIDES, BILOBADIDE) FROM
LEAVES AND PHARMACEUTICAL POWDERS OF GINKGO BILOBA

of which the following is a full, clear and exact description.

5 **METHOD FOR ISOLATING TERPENE**
 TRILACTONES (GINKGOLIDES, BILOBALIDE)
 FROM LEAVES AND PHARMACEUTICAL POWDERS OF GINKGO BILOBA

 This application is a continuation-in-part of U.S. Serial
 No. 09/903,049, filed July 11, 2001, the contents of which
10 are hereby incorporated by reference.

 Throughout this application various publications are
 referenced in parenthesis. The disclosures of these
 publications in their entireties are hereby incorporated by
15 reference into this application in order to more fully
 describe the state of the art to which this invention
 pertains.

Background of the Invention

20 *Ginkgo biloba* fruits and seeds have been long used in
 Chinese folk medicine. The first mentioning of such a use
 appeared in the book of Liu Wen-Tai in 1505 in China. In
 the 1960's the structures of the active components have
 been analyzed. Around the same time, in 1965 the first leaf
25 preparations were placed in modern medicine by the Willmar
 Schwabe AG, Germany. In 1971 after a collaboration between
 the Willmar Schwabe AG, Germany and the Beaufour group
 (IPSEN) in France the first concentrated and standardized
 extract EGb761 (Germany 1971: DE 2117429 C3 and France
30 1972: 72.12288) were launched and commercialized as Tanakan
 (France) and Tebonin Forte (Germany). Following the
 European application, in 1977 a leaf extract was described
 in the Medical Dictionary of the Republic of China. During
 the next decade other companies also placed similar
35 products on the market. Today, *Ginkgo biloba* leaf extracts

are found in several kinds of products, such as food supplements and energy pills, homeopathic uses, juices, cosmetics, various tea preparation, cigarettes, Ginkgo wine or and even in potato snacks referred to as the 'memory snack'. The biological activities from the extracts are diverse and known to be effective in: increasing short-term memory, treatment of cerebral insufficiency and dementia, beneficial effects as an antiasthmatic and against polyuria or tinitus, PAF-inhibitor and improving the blood flow, vaso-protection and radical scavenging.

Since the current extract Egb761 contains only between 5-7% of this terpene trilactones, the extract is only used as a food and health supplement. In order to further enhance the market for *Ginkgo biloba* products, the interest is geared towards extracts with higher purity. In contrast to the large number of patents, where the extraction procedure is rather complicated or the terpene trilactones can only be obtained in a low purity, disclosed herein is a simple extraction procedure for producing a terpene trilactones concentration that is 10-fold higher. Disclosed is a method of isolation and concentration of the terpene trilactones from leaves of the tree *Ginkgo biloba* or from pharmaceutical powder can be used on the industrial scale.

25

Summary of the Invention

Disclosed is a method of isolating terpene trilactones from *Ginkgo biloba* plant material or extract comprising the
5 steps of suspending the plant material or extract in either water or an aqueous solution of an oxidation reagent; extracting the terpene trilactones using an acceptable extraction agent; separating the organic layer from the aqueous layer; washing the organic layer with an acceptable
10 aqueous salt solution, which may be an alkaline solution; and drying the organic layer to form a dried extract containing terpene trilactones. Further processing by reversed phase chromatography of the extracts with polymeric resins reduces the level of undesirable ginkgolic
15 acids to amounts less than 10 ppm.

Detailed Description of the Invention

One embodiment of the subject invention is a method of isolating terpene trilactones from *Ginkgo biloba* plant material or extract comprising the steps of:

suspending the plant material or extract in the presence of an oxidation reagent,

extracting the terpene trilactones using an acceptable extraction agent, and

separating the organic layer from the aqueous layer to thereby isolate the terpene trilactones in the organic layer. The oxidation reagent may be in aqueous solution.

In the method, the aqueous solution may contain 0.1% to 50% oxidation reagent, preferably 0.1% to 30%, more preferably 1% to 20%, yet more preferably 2% to 15%, most preferably 3% to 5%. The oxidation reagent may be any oxidizing agent, and can be 3-chloroperbenzoic acid (MCPBA), MnO_2 , or hydrogen peroxide. The oxidation reagent is preferably hydrogen peroxide.

In the method, the aqueous solution may further comprises an acid. The amount of acid in the aqueous solution may be from about 0.1% to 15%, or as otherwise necessary to make an acidic environment. The acid may be selected from the group consisting of acetic acid, hydrochloric acid, nitric acid, phosphoric acid and sulfuric acid.

In the method, the acceptable extraction agent may be selected from the group consisting of lower acetates, lower ketones, lower ether, lower alcohols and benzenes.

The method may further comprise at least a first washing step to wash the organic layer with an acceptable aqueous

salt solution. The acceptable aqueous solution may be a solution of a salt or hydroxide selected from the group consisting of ammonium chloride, sodium carbonate, sodium bicarbonate, potassium carbonate, sodium hydroxide, potassium hydroxide, sodium thiosulfate, sodium sulfite and sodium hydrosulfide. The acceptable aqueous salt solution may preferably be a solution of a salt selected from the group consisting of sodium thiosulfate, sodium sulfite and sodium hydrosulfide.

10

Preferably the aqueous salt or hydroxide solution is at a pH between 5 and 14, more preferably pH 7-14, or pH 6-12, yet more preferably pH 7.5-9.5, most preferably pH 8.3-9.3. Generally, the preferred pH of the aqueous salt or hydroxide solution is an alkali pH, thus making an aqueous alkali salt or hydroxide solution.

The aqueous alkali solution may be also an alkali hydroxide aqueous solution such as a sodium hydroxide solution or a potassium hydroxide solution.

The method may further comprising a second washing step to wash the organic layer with an acceptable aqueous salt or hydroxide solution. The acceptable aqueous salt or hydroxide solutions of the second wash step is selected from the group consisting of ammonium chloride, sodium carbonate, sodium bicarbonate, potassium carbonate, sodium hydroxide, potassium hydroxide, sodium thiosulfate, sodium sulfite and sodium hydrosulfide. The second washing step may be performed with a solution that is different from the solution used in the first washing step.

The method may further comprise a step to destroy excess oxidation reagent in the organic layer by contacting the

organic layer with a metal containing catalyst or a nonmetal catalyst.

5 The method may further comprise a step of drying the organic layer to form an extract containing terpene trilactones. The dried extract contains more than 50% by weight terpene trilactones, preferably more than 55%, yet more preferably more than 60%.

10 The method may further comprise a step of recrystallizing the extract containing terpene trilactones to obtain terpene trilactones in higher purity. The recrystallization may be performed with an acceptable solvent or solvent mixture.

15 The method may further comprise a step of purification by treatment with or filtration over activated charcoal.

20 The method may further comprise a step of purification by treatment with or filtration over alumina, such as aluminum oxide.

Another embodiment of the subject inventions is a method of isolating terpene trilactones from *Ginkgo biloba* plant material or extract comprising the steps of:

- 25 suspending the plant material or extract in an aqueous solution of an oxidation reagent;
- extracting the terpene trilactones using an acceptable extraction agent;
- 30 separating the organic layer from the aqueous layer;
- washing the organic layer with an acceptable aqueous salt or hydroxide solution; and
- drying the organic layer to form a dried extract containing terpene trilactones, thereby isolating the

terpene trilactones.

The parameters of this embodiment may be as discussed above for the previous method. Similarly, any additional steps
5 as discussed above may be present in this embodiment.

This method, as well as the previous method, may further comprise a step of heating or boiling the suspended plant material or extract in aqueous solution for a period of
10 time between 5 minutes and 5 hours.

This method, as well as the previous method, may further comprise a step of adjusting the pH of the suspended plant material or extract in aqueous solution to a range of about
15 pH 4 and pH 6.5.

Yet another embodiment is a method of isolating terpene trilactones from *Ginkgo biloba* plant material or extract comprising the steps of:

20 suspending the plant material or extract in an aqueous solution of hydrogen peroxide;
adjusting the pH of the suspended plant material or extract in aqueous solution to a pH of between 4 and 6.5;
extracting the terpene trilactones using an acceptable
25 extraction agent;
separating the organic layer from the aqueous layer;
washing the organic layer with an aqueous alkaline salt or hydroxide solution;
drying the organic layer to form a dried extract
30 containing terpene trilactones; and
recrystallizing the dried extract containing terpene trilactones to obtain terpene trilactones in higher purity to thereby isolate the terpene trilactones.

The parameters of this embodiment may be as discussed above for the previous two embodiments. Similarly, any additional steps as discussed above may be present in this embodiment.

5

In this embodiment, the aqueous solution may contain 0.1% to 30% hydrogen peroxide. The recrystallization may be performed with an acceptable solvent or solvent mixture.

10 The method may further comprise a step of purification by treatment with or filtration over activated charcoal.

The method may further comprise a step of purification by treatment with or filtration over alumina, such as aluminum
15 oxide.

A further embodiment is a method of isolating terpene trilactones from *Ginkgo biloba* plant material or from an extract comprising the steps of:

20 suspending the plant material or extract in water;
extracting the terpene trilactones using an acceptable extraction agent;
separating the organic layer from the aqueous layer;
washing the organic layer with an aqueous alkaline
25 salt or hydroxide solution;
to thereby isolate the terpene trilactones in the organic layer.

The parameters of this embodiment may be as discussed above
30 for the previous embodiments. Similarly, any additional steps as discussed above may be present in this embodiment.

In this embodiment, the separation may be performed with the addition of sodium chloride to the emulsion containing

organic and aqueous layers. The aqueous alkaline salt solution may also be a sodium sulfite solution.

5 The terpene trilactones from any of the embodiments can be purified by further processing, for example by reversed phase chromatography, to reduce any unwanted ginkgolic acids. For example, chromatography can be performed with silica gel.

10 The method of isolating and concentrating terpene trilactones (ginkgolides A,B,C,J and bilobalide) from leaves of the tree *Ginkgo biloba* or from pharmaceutical powder produced by extraction of the leaves of *Ginkgo biloba*, for example Egb761, can generally proceed by the
15 following procedures:

- (A) Suspend the dried leaves or the pharmaceutical powder
1) in water, or 2) in an aqueous solution containing
hydrogen peroxide at a concentration range of 0.1-30%,
20 or 3) in an aqueous solution containing hydrogen peroxide at a concentration range of 0.1-30% and additional 0.1-15% percent of mineral acids like acetic, hydrochloric, nitric, phosphoric or sulfuric acid;
- 25 (B) Stir only, stir and heat, or stir and boil the suspension of (A) for a period of time between 5 min to 5 hours;
- (C) If necessary, adjust the pH after this treatment to a range of pH 4-6 with alkali hydroxide aqueous
30 solutions such as sodium hydroxide or potassium hydroxide;
- (D) Extract the suspension of (B) or (C) with lower acetates, lower ketones, lower ether, lower alcohols

or benzenes, separate the organic layer from the aqueous solution;

- 5 (E) Wash the organic layer 1) with an aqueous based solution, such as ammonium chloride, sodium carbonate, sodium bicarbonate, potassium carbonate or with alkali hydroxide aqueous solutions such as sodium hydroxide or potassium hydroxide, or 2) with an aqueous solutions such as sodium thiosulfate, sodium sulfite and sodium hydrosulfide or destroy the excess of
10 hydrogen peroxide with metal dust or on metal based catalysts, or both of 1) and 2);
- (F) Wash the organic layer with water and/or with an aqueous solution of sodium chloride;
- 15 (G) Separate, dehydrate and dry the remaining organic layer, remove solvent and obtain an extract which contains more than 50 % terpene trilactones; and
- (H) Recrystallize the extract from step (G) with a mixture of water/methanol or any other acceptable solvent system to obtain the ginkgolides in high purity.

20

The parameters and characteristics of each of the embodiments described above are interchangeable when applicable to each other, and are therefore not repeated. Thus, for example, any parameter or characteristic of the
25 first embodiment may be employed in the other embodiments of the invention.

EXPERIMENTAL DETAILS

In the following examples, the invention is described in details. All examples produce an extract, which contains between 55% and 75% of terpene trilactones before
5 recrystallization. After recrystallization with a water/methanol mixture, the terpene trilactones were obtained in high purity. Besides resulting in a higher purity and higher yields, the disclosed method is performed in a decreases time for the extraction process thus helping
10 to save energy. Also, in this method, the water and organic layers are simple to separate, the method maintains the natural distribution of the terpene trilactones levels, and gives high recovery of the terpene trilactones.

15 EXAMPLE 1

250 g of dried leaves from *Ginkgo biloba* was suspended in 2 L 5% hydrogen peroxide aqueous solution and boiled for 1 h. The suspension was hot filtrated through a Büchner funnel without filter paper. The remaining leaf fibers
20 were washed with 2x 100 mL water by vaccum filtration. The filtrate was then extracted first with 250 mL ethyl acetate, then a second time with 125 mL ethyl acetate. The organic layers were combined followed by the washing procedure. First washing 3x (200 mL, 100 mL, 100 mL) with
25 a saturated aqueous solution of sodium bicarbonate, second 2x (200 mL, 100 mL) with a saturated aqueous solution of sodium sulfite and third with 100 mL water and then with 100 mL sodium chloride solution (80%). After this washing procedure the organic layer was dried over sodium sulfate
30 and the solvent removed. The resulting 830 mg powder contained 52% terpene trilactone, quantified by NMR. The ratio between the terpene trilactones BB : GA : GB : GC : GJ with 4.8 (57%) : 1.4 (16%) : 1.0 (12%) : 0.9 (11%) : 0.3 (4%) followed the natural distribution pattern.

EXAMPLE 2

250 g of dried leaves from *Ginkgo biloba* was suspended in 2.5 L 5% hydrogen peroxide aqueous solution and boiled for 1 h. The suspension was hot filtrated through a Büchner funnel without filter paper. The remaining leaf fibers were washed with 2x 100 mL water by vacuum filtration. The pH of the filtrate was adjusted to 4.5 by addition of an 1 N aqueous solution of sodium hydroxide. After this treatment, the water solution was extracted first with 300 mL of a 2:1 mixture of ethylacetate and diethylether and second with 150 mL of the same mixture. The organic layers were combined followed by the washing procedure. First washing 3x (200 mL, 100 mL, 100 mL) with a saturated aqueous solution of sodium bicarbonate, second 2x (200 mL, 100 mL) with a saturated aqueous solution of sodium thiosulfate and third with 100 mL water and finally with 100 mL sodium chloride solution (80%). After this washing procedure the organic layer was dried over sodium sulfate and the solvent removed. The resulting powder contained 50% terpene trilactones, quantified by NMR.

EXAMPLE 3

25 g of pharmaceutical extract powder from *Ginkgo biloba* was suspended in 500 mL 5% hydrogen peroxide aqueous solution and boiled for 1 h. After cooling to room temperature, the suspension was filtrated through a Büchner funnel without filter paper. Afterwards, the filtrate was extracted first with 250 mL ethyl acetate, then a second time with 125 mL ethyl acetate. After separation from the water layer, the organic layers were combined followed by the washing procedure. First washing 3x (200 mL, 100 mL, 100 mL) with a saturated aqueous solution of sodium bicarbonate, second 2x (200 mL, 100 mL) with a saturated

aqueous solution of sodium sulfite and third with 100 mL water and finally with 100 mL sodium chloride solution (80%). After this washing procedure the organic layer was dried over sodium sulfate and the solvent removed. The
5 resulting 3.4 g powder contained 55% terpene trilactone, quantified by NMR.

EXAMPLE 4

25 g of pharmaceutical extract powder from *Ginkgo biloba*
10 was suspended in a 500 mL 5% hydrogen peroxide aqueous solution and boiled for 30 min. After cooling to room temperature, the suspension was filtrated through a büchner funnel without filter paper. The filtrate was extracted first with 250 mL ethyl acetate, then a second time with
15 125 mL ethyl acetate. The organic layers were combined followed by washing 3x with a saturate aqueous solution of sodium sulfite (200 mL, 100 mL, 50, mL) afterwards with 100 mL water and finally with 100 mL sodium chloride solution (80%). After this washing procedure the organic layer was
20 dried over sodium sulfate and the solvent was removed. The resulting 2.8 g contained 60% terpene trilactones, quantified by NMR.

EXAMPLE 5

25 25 g of pharmaceutical extract powder from *Ginkgo biloba* was suspended in 500 mL water and boiled for 30 min. After cooling to room temperature, this suspension was extracted with ethyl acetate (1st with 250 mL, 2nd with 50 mL). Without
hydrogen peroxide a emulsion was obtained, but the layers
30 of this emulsion separated slower than the procedure using hydrogen peroxide. After filtration and adding sodium chloride, the layers separated. The organic layers were combined followed by washing 3x with a saturated aqueous

solution of sodium sulfite (200 mL, 100 mL, 50 mL), afterwards washed with 100 mL water and finally with 100 mL sodium chloride solution (80%). After this washing procedure the organic layer was dried over sodium sulfate and the solvent was removed. The resulting 3.0 g powder contained 53% terpene trilactone, quantified by NMR.

EXAMPLE 6

25 g of pharmaceutical extract powder from *Ginkgo biloba* was suspended in 500 mL 5% hydrogen peroxide aqueous solution, containing additional 1 % of sulfuric acid and boiled for 15 min. The suspension was hot filtrated through a büchner funnel without filter paper. After cooling to room temperature, the filtrate was extracted first with 250 mL ethyl acetate, then a second time with 125 mL ethyl acetate. After separation from the water layer, the organic layers were combined followed by the washing procedure. First washing 3x (200 mL, 100 mL, 100 mL) with a saturated aqueous solution of sodium bicarbonate, second 2x (200 mL, 100 mL) with a saturated aqueous solution of sodium sulfite and third with 100 mL water and then with 100 mL sodium chloride solution (80%). After this washing procedure the organic layer was dried over sodium sulfate and the solvent removed. The resulting 1.9 g powder contained 70% terpene trilactone, quantified by NMR.

EXAMPLE 7

25 g of pharmaceutical extract powder from *Ginkgo biloba* was suspended in 500 mL 5% hydrogen peroxide aqueous solution, containing additional 1 % of acetic acid and boiled for 30 min. After cooling to room temperature, the suspension was passed through a büchner funnel without filter paper. The filtrate was extracted first with 250 mL

ethyl acetate, then a second time with 125 mL ethyl acetate. The organic layers were combined followed by the washing procedure. First washing 3x (200 mL, 100 mL, 100 mL) with a saturated aqueous solution of sodium bicarbonate, 5 second 2x (200 mL, 100 mL) with a saturated aqueous solution of sodium thiosulfite. Afterwards washing with 100 mL water and then with 100 mL sodium chloride solution (80%) for removing base and salt excess. After this washing procedure the organic layer was dried over sodium 10 sulfate and the solvent was removed. The resulting 2.8 g powder contained 59% terpene trilactone, quantified by NMR.

EXAMPLE 8

25 g of pharmaceutical extract powder from *Ginkgo biloba* 15 was suspended in 500 mL 5% hydrogen peroxide aqueous solution and boiled for 1 h. After cooling to room temperature, the suspension was filtrated through a büchner funnel without filter paper. The pH of the filtrate was adjusted to 5-6 by addition of 1 N aqueous solution of 20 sodium hydroxide. After this treatment, the water solution was extracted first with 250 mL ethyl acetate, then a second time with 125 mL ethyl acetate. After separation from the water layer, the organic layers were combined followed by the washing procedure. First washing 3x (200 25 mL, 100 mL, 100 mL) with a saturated aqueous solution of sodium bicarbonate, second 2x (200 mL, 100 mL) with a saturated aqueous solution of sodium sulfite and third with 100 mL water and then with 100 mL sodium chloride solution (80%). After this washing procedure the organic layer was 30 dried over sodium sulfate and the solvent removed. The resulting 2.73 g powder contained 60% terpene trilactone, quantified by NMR.

EXAMPLE 9

Some leaf extracts possessed a significant amount of the generally undesired ginkgolic acids.

5

Ginkgolic acids.

10 The ginkgolic acids were removed by reversed-phase chromatography. (Chang, M.) The content of the two predominant ginkgolic acids found in *G. biloba* leaves were measured by HPLC using PDA detection; in each case measured, the individual ginkgolic acids were present in
15 amounts lower than the limit of quantitation (10 ppm).

General Experimental Procedures.

^1H and ^{13}C Spectra were acquired on either a 300 or 400 MHz Bruker NMR using standard pulse sequences and parameters;
20 further details are described below. Negative ion FABMS data were determined using a JMS-HX110 Tandem Mass spectrometer (JEOL, Tokyo Japan) instrument using Xe beam (6 kV) with a 10 kV acceleration voltage and m-nitrobenzyl alcohol (NBA) matrix. Analytical HPLC measurements were
25 performed on a Waters 996 PDA system with a MilleniumTM Version 2.15.01 software package. Concentration graphs and linear regression were determined with Microsoft Excel[®] 2000. Semipreparative HPLC isolations were achieved on a LC-908 (Japan Analytical Industry Co., Ltd.) instrument
30 equipped with internal refractive index and ultraviolet detectors and a recorder.

Extract Material.

Bioginkgo™ 27/7 brand *G. biloba* extract was generously donated by Pharmanex (Provo, UT).

5 Plant Material.

The leaves were collected from a female *G. biloba* tree in Morningside Park, New York, New York. Yellow leaves were collected (having fallen to the ground) in Nov. 2000 and green leaves were collected in Jun. 2001. They were frozen
10 in liquid nitrogen, crushed and lyophilized until constant weight. The moisture content was 59% in the yellow leaves and 73% in green leaves. Further samples of these leaves are stored in our laboratory.

15 General Extraction of TTLs.

Bioginkgo™ 27/7 extract (25 g) or lyophilized leaves (250 g) were boiled for 1 h in 0.5 L (extract) or 2 L (leaves) aqueous 5% aq. H₂O₂ (or other oxidation reagents in water). After passing (extract = RT, leaves = boiling) through a
20 Buchner funnel w/o filter paper, the remaining solution was extracted up to 3 times w/EtOAc (250/125/75 mL). The organic layer was washed w/sat. aq. salt solution (NaHCO₃/Na₂S₂O₃ NaHCO₃/Na₂SO₃ or Na₂SO₃) followed by water and 80% aq. NaCl. (saturated aq. solution diluted to 80%).
25 After drying over Na₂SO₄, solvent was removed to yield an amorphous yellow powder with 50-60% TTL content. See, Figure 6.

For further purification these extracts were dissolved in
30 EtOAc and passed through an activated charcoal column. Concentration gave an off-white amorphous powder w/60-70% content of TTLs. A more rigorous procedure involved dissolving the extracts in methanol, adding activated charcoal, and filtering over Celite 545.

TLC Analysis of TTLs.

Thin layer chromatography of TTLs was performed as previously reported. (van Beek, 1993)

5 HPLC separation of TTLs.

A 1 X 25 cm 5m YMC ODS-AM column with a 1 mL/min H₂O:MeOH:THF (7:2:1) solvent system was used to separate the TTLs; monitoring was performed with a refractive index detector. (O'Reilly)

10

Removal of ginkgolic acids.

Ginkgolic acids were removed from the extracts by reversed-phase chromatography using polymeric resins such as Dionan® HP-20 (Chang, M.) or Amberlite® XAD-16 with a step gradient of increasing methanol (30-90%) in water. TTL containing fractions (40-80%, as determined by NMR or TLC) were combined and the solvent was removed to afford the final products. WP C18 silica was also employed (twice) with aq. 60% methanol successfully to remove ginkgolic acids.

20

Extraction of ginkgolic Acids.

Standards were isolated from hexane-extracted *G. biloba* leaves that were subjected to chromatography with silica gel (1% MeOH in CHCl₃), RP-18 silica gel (0-100% MeOH, retaining the 100% MeOH fraction), and semi-preparative HPLC (1 X 25 cm 5m YMC ODS-AM column, H₂O:MeOH:AcOH(100:10:1) solvent system, monitored at 215 nm). Spectroscopic analyses of these compounds (¹H NMR, ¹³C NMR, and negative mode FABMS) provided results similar to those previously reported. (Itokawa, H.)

30

Quantitation of ginkgolic Acids.

Ginkgolic acid standards (3, 5, 25, 50, 250 hg) in MeOH (5 mL) were injected onto a 4.6 X 150 mm Phenomenex® Luna 5 m

C18(2) column with 0.1% TFA in MeCN solvent system (flow rate = 1 mL/min) and detection at 215 nm; concentration graphs showing good linearity ($R^2 \geq 0.99$). Multiple injections determined the level of quantitation to be 10 ppm. Samples were prepared by dissolving 1-2 mg of extract in 100 mL MeOH; 20 mL injections were then analyzed in a similar fashion.

DISCUSSION

An efficient and rapid protocol has been developed for extracting ginkgolides and bilobalide (terpene trilactones, TTLs) from *Ginkgo biloba* leaves. The procedure takes advantage of the extraordinary stability, despite the presence of multiple oxygen functions, of the TTL structure to a variety of chemical treatments, especially oxidation. The protocol involves boiling the aqueous extract of leaves with dilute hydrogen peroxide, extraction with ethyl acetate, washing with basic solutions, and charcoal filtration to yield off-white powder, TTL content 60-70 %. Presumably the hydrogen peroxide treatment degrades undesired leaf constituents that lead to intense emulsification during extractions. Further reversed phase chromatography of the extracts with polymeric resins removes the undesirable ginkgolic acids to amounts less than 10 ppm. The extracts are suited for pure TTL preparation, enrichment of TTL content in nutraceuticals, and preparations of low-flavonoid / high-TTL controls in medicinal studies.

EGB 761, (Polich, J.) a standardized extract of the leaves, contains 5-7% ginkgolides (Kennedy, D. O.; DeFeudis, F. V.) and bilobalide (BB) (Braquet P.) (terpene trilactones, TTLs) along with 22-24% flavonoids and less than 5 ppm ginkgolic acids (also known as anacardic acids). (Polich,

J.) This limit was imposed because alkylphenols such as ginkgolic acids have been reported to induce contact dermatitis (Ishii, S.; Kato, K.); cytotoxicity was also reported for these compounds. (Bito, H.)

5

An efficient and economical extraction of TTLs is essential to secure the amounts of materials required for bioorganic and other studies. In contrast to conventional isolation procedures, which are tedious and lengthy, (O'Reilly, J.)
10 the method described concentrates the TTLs in the leaves (ca. 0.2%) to 70% in three rapid steps of oxidation, extraction and washing. The clear advantage is that, at least at the laboratory scale, the extraction is shortened from several days to one day because of minimal emulsion
15 formation in the EtOAc extraction process, and that only a single common organic solvent is used. The resulting extracts are ideal as starting material for pure TTL preparation from leaves, for enriching TTL content in dietary supplements, and as low-flavonoid/high-TTL controls
20 in medicinal studies.

Quantitative NMR analyzed the TTLs in the extracts (van Beek, 1993) by taking advantage of the 12-H signals, which in all TTLs appear as well separated singlets. Using the
25 two olefinic protons of maleic acid as an internal standard, DMSO was used instead of the solvent mixture originally described, and a small amount of acetic acid was added to avoid peak shifts in the 12-H region of the spectrum. See, Figure 5.

30

During structural studies of ginkgolides it was found that they are cage compounds of extraordinary stability despite the presence of many oxygen functions (Maruyama, M.). They are unaffected by boiling in conc. nitric acid, alkali

fusion of GA merely results in expulsion of C-10/C-11 to generate a hemiacetal, while treatment of GA in conc. sulfuric acid with sodium dichromate simply converted the hydroxy lactone to its oxolactone. Utilizing this
5 extraordinary stability, we investigated various oxidation conditions and subsequent workup to destroy/remove components other than TTLs in the leaves.

The process is composed of boiling the TTL-containing
10 material in water with a oxidizing agent, filtering, extracting the filtrate with ethyl acetate, washing the organic phase with basic solutions, and solvent removal. These extraction processes were first optimized with a *G. biloba* extract (Pharmanex Bioginkgo™ 27/7, 27% flavonoids
15 / 7% TTLs) and then applied to leaves. Several oxidizing reagents such as hydrogen peroxide, 3-chloroperbenzoic acid (MCPBA) and MnO₂ were tested for extraction suitability of TTLs from Bioginkgo™ powder. The yields and percent contents of TTLs of the extracts boiled with H₂O₂, MCPBA and
20 pure water were similar, i.e., 55% TTLs. There was a significant decrease in the yield after MnO₂ treatment due to destruction of BB (which is much less stable than the ginkgolides) but the amounts of ginkgolides also decreased, probably due to absorption onto solid MnO₂. Further
25 investigations were focused on H₂O₂ as it was the only oxidizing agent that provided distinct layer separation during extraction, while the other agents resulted in emulsions with lower recovery of TTLs; it is likely that the H₂O₂ treatment destroys the ingredient(s) leading to
30 tenacious emulsification in the step involving extraction into the organic layer (ethyl acetate).

The concentration of H₂O₂ was varied to determine the optimal concentration. With washing, the total amount of

extract decreased with higher percentages of H_2O_2 , but without washings the opposite was observed. Good separation of layers was found for 5% and 10% H_2O_2 , whereas 1% H_2O_2 gave an emulsion and 3% H_2O_2 required more time for layer separation. The highest recoveries of TTLs with washing were found for 3% and 5% H_2O_2 . After extraction, H_2O_2 was detected in the organic layer (by the color change on filter paper impregnated with potassium iodide) and in the case of 10% H_2O_2 , the excess peroxide gave rise to an exothermic reaction upon workup. Therefore 5% H_2O_2 was used in all further investigations. With respect to the boiling time, 1 h. was found to be optimal.

The Bioginkgo™ powder as well as leaves gave rise to acidic water (pH 3) after boiling. Since peroxide oxidation should work better under acidic conditions, oxidation with 5% H_2O_2 and additional 1% of several acids were tested. The results were either no change or decreased recovery of TTLs. It was thus concluded that use of aqueous H_2O_2 without additional acid was optimal.

After boiling with peroxide, all mixtures were extracted three times with EtOAc. With respect to the number of extraction, three turned out to be sufficient. For leaf extractions, a precipitate present in the organic layer had to be removed by filtration. Washing the EtOAc layer with basic solutions was critical for high TTL content. Base was used to neutralize organic acids and to destroy peroxide excess, but the lactones in the TTLs could open under such treatment, resulting in increased water solubility. For GB it was reported that lactones start opening at pH 6.5. (Zekri, O) As expected, aqueous Na_2CO_3 (pH 10.4) and NaSH (pH 10.8) resulted in lower recovery yields of TTLs, with BB and ginkgolide C (GC) no longer

detected in the extract. However, washing with saturated solutions of NaHCO_3 and $\text{Na}_2\text{S}_2\text{O}_3$ (both pH 8.3) and Na_2SO_3 (pH 9.3) led to consistent extraction yields and high TTL content. Further workup yielded extracts containing 50-70% TTLs. In contrast to basic solutions, use of aqueous NH_4Cl (pH 5) was not effective in removing impurities.

Since the lactones of TTLs are closed at pH 3, the presence of any TTL in the discarded aqueous layer after washing with Na_2SO_3 (pH 9.3) was tested after acidification of the combined water layers with 1 N HCl; no TTLs were detected by TLC. Using the same procedure for the water layers after washing with Na_2CO_3 (pH 10.4), GC and decomposition products of BB were found.

15

A typical extract prepared from Bioginkgo™ 27/7 is shown in Figure 7A. Small quantities of pure TTLs were obtained from such extracts with semi-preparative reversed-phase HPLC (Teng, B. P.); larger quantities can be purified by a number of different procedures. (Teng, B. P.; van Beek 1997)

After optimization, the protocol was applied to dried leaves. The total TTL contents were similar for the treated Bioginkgo™ 27/7 powder (65%), the yellow leaves (65%) and the green leaves (70%) (Figure 7).

The content of TTLs in leaves depends on seasons and other factors such as tree age. (Laurain, D.) As described for leaves and for EGb761 (26% flavonoids, 6% TTL), BB was always the major component of the TTL content (ca. 50%). (van Beek, 1992; Sticher, O) The procedures described led to minimal BB destruction, high recovery yield and maintained a natural distribution pattern.
